

# JavaScript: Functions

# 9.1 Introduction

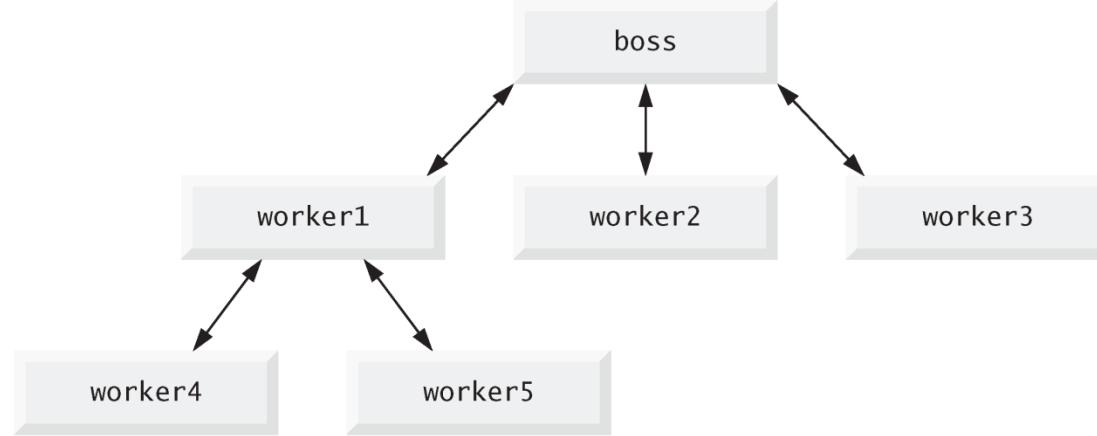

- To develop and maintain a large program
  - Construct it from small, simple pieces
  - Divide and conquer

## 9.2 Program Modules in JavaScript

- You'll combine new functions that you write with prepackaged functions and objects available in JavaScript
- The prepackaged functions that belong to JavaScript objects (such as **Math.pow**, introduced previously) are called methods
- JavaScript provides several objects that have a rich collection of methods for performing common
  - Mathematical calculations
  - String manipulations
  - Date and time manipulations
  - Manipulations of arrays

## 9.2 Program Modules in JavaScript (Cont.)

- You can define programmer-defined functions that perform specific tasks and use them at many points in a script
  - The actual statements defining the function are written only once and are hidden from other functions
- Functions are invoked by writing the name of the function, followed by a left parenthesis, a comma-separated list of zero or more arguments, followed by a right parenthesis
- Methods are called in the same way as functions, but require the name of the object to which the method belongs and a dot preceding the method name
- Function (and method) arguments may be constants, variables or expressions

---

**Fig. 9.1 |** Hierarchical boss-function/worker-function relationship.

## 9.2 Program Modules in JavaScript (Cont.)

- **total += parseFloat( inputValue );**
  - When this statement executes, the JavaScript function **parseFloat** converts the string in the **inputValue** variable to a floating-point value and adds that value to **total**
  - Variable **inputValue** is function **parseFloat**'s argument
    - Function **parseFloat** takes a string representation of a floating-point number as an argument and returns the corresponding floating-point numeric value
- Methods are called in the same way but require the name of the object to which the method belongs and a dot preceding the method name
  - **document.writeln("Hi there.");**

## 9.3.1 Programmer-Defined Function square

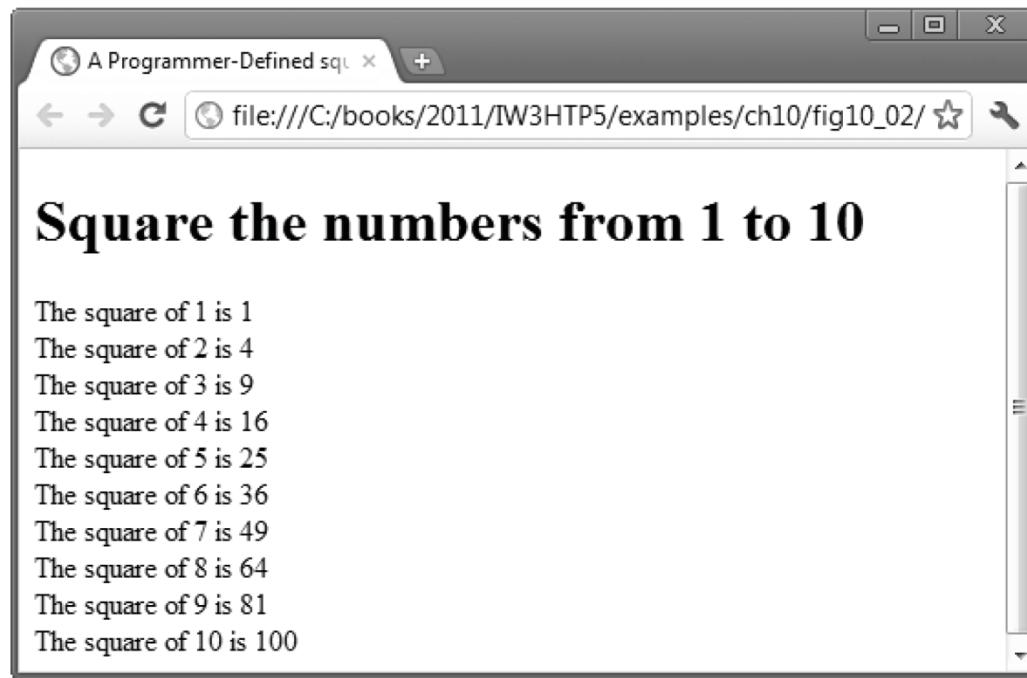

- **return** statement
  - Pass information from inside a function back to the point in the program where it was called
- A function must be called explicitly for the code in its body to execute
- The format of a function definition is
  - **function function-name( parameter-list )**
  - {
  - declarations and statements**
  - }

```
1  <!DOCTYPE html>

3  <!-- Fig. 9.2: SquareInt.html -->
4  <!-- Programmer-defined function square. -->
5  <html>
6      <head>
7          <meta charset = "utf-8">
8          <title>A Programmer-Defined square Function</title>
9          <style type = "text/css">
10         p { margin: 0; }
11     </style>
12     <script>
13
14         document.writeln( "<h1>Square the numbers from 1 to 10</h1>" );
15
16         // square the numbers from 1 to 10
17         for ( var x = 1; x <= 10; ++x )
18             document.writeln( "<p>The square of " + x + " is " +
19                             square( x ) + "</p>" );
20
```

**Fig. 9.2 |** Programmer-defined function square. (Part 1 of 3.)

```
21      // The following square function definition's body is executed
22      // only when the function is called explicitly as in line 19
23  function square( y )
24  {
25      return y * y;
26  } // end function square
27
28  </script>
29  </head><body></body> <!-- empty body element -->
30 </html>
```

**Fig. 9.2 |** Programmer-defined function square. (Part 2 of 3.)

A screenshot of a web browser window titled "A Programmer-Defined sql". The address bar shows "file:///C:/books/2011/IW3HTP5/examples/ch10/fig10\_02/". The main content area displays the following text:

## Square the numbers from 1 to 10

The square of 1 is 1  
The square of 2 is 4  
The square of 3 is 9  
The square of 4 is 16  
The square of 5 is 25  
The square of 6 is 36  
The square of 7 is 49  
The square of 8 is 64  
The square of 9 is 81  
The square of 10 is 100

**Fig. 9.2** | Programmer-defined function `square`. (Part 3 of 3.)

### **Common Programming Error 9.1**

---

Forgetting to return a value from a function that's supposed to return a value is a logic error.

## 9.3.1 Programmer-Defined Function square (cont.)

- Three ways to return control to the point at which a function was invoked
  - Reaching the function-ending right brace
  - Executing the statement “return;”
  - Executing the statement “return expression;” to return the value of expression to the caller
- When a return statement executes, control returns immediately to the point at which the function was invoked

## 9.3.2 Programmer-Defined Function maximum (cont.)

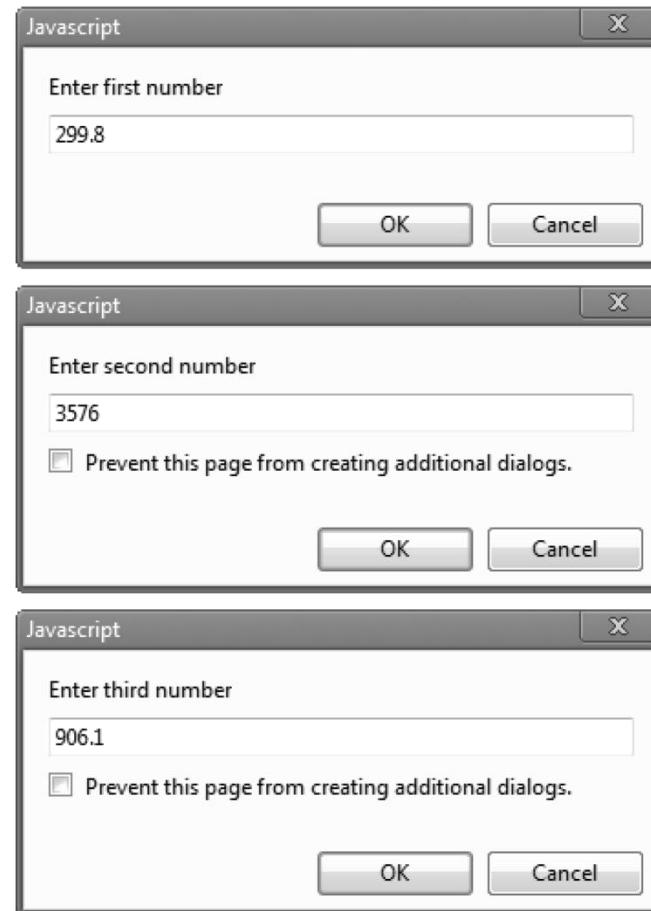

- The script in our next example (Fig. 9.3) uses a programmer-defined function called maximum to determine and return the largest of three floating-point values

```
1  <!DOCTYPE html>
2
3  <!-- Fig. 9.3: maximum.html -->
4  <!-- Programmer-Defined maximum function. -->
5  <html>
6      <head>
7          <meta charset = "utf-8">
8          <title>Maximum of Three Values</title>
9          <style type = "text/css">
10             p { margin: 0; }
11         </style>
12         <script>
13
14             var input1 = window.prompt( "Enter first number", "0" );
15             var input2 = window.prompt( "Enter second number", "0" );
16             var input3 = window.prompt( "Enter third number", "0" );
17
18             var value1 = parseFloat( input1 );
19             var value2 = parseFloat( input2 );
20             var value3 = parseFloat( input3 );
21
22             var maxValue = maximum( value1, value2, value3 );
23
```

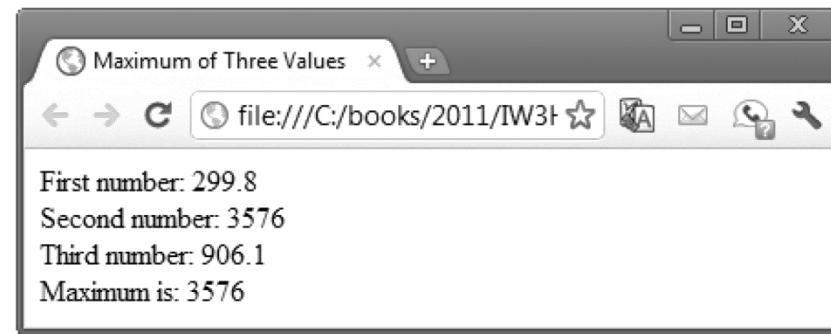

**Fig. 9.3 |** Programmer-defined maximum function. (Part 1 of 4.)

```
24     document.writeln( "<p>First number: " + value1 + "</p>" +
25         "<p>Second number: " + value2 + "</p>" +
26         "<p>Third number: " + value3 + "</p>" +
27         "<p>Maximum is: " + maxValue + "</p>" );
28
29     // maximum function definition (called from line 22)
30     function maximum( x, y, z )
31     {
32         return Math.max( x, Math.max( y, z ) );
33     } // end function maximum
34
35     </script>
36     </head><body></body>
37 </html>
```

# 9.4 Notes on Programmer-Defined Functions

- All variables declared with the keyword **var** in function definitions are local variables
  - They can be accessed only in the function in which they're defined
- A function's parameters are also considered to be local variables
- There are several reasons for modularizing a program with functions
  - Divide-and-conquer approach makes program development more manageable
  - Software reusability
  - Avoid repeating code in a program

## Software Engineering Observation 9.1

If a function's task cannot be expressed concisely, perhaps the function is performing too many different tasks. It's usually best to break such a function into several smaller functions.

## Software Engineering Observation 9.2

To promote software reusability, every function should be limited to performing a single, well-defined task, and the name of the function should describe that task effectively. Such functions make programs easier to write, debug, maintain and modify.

## Good Programming Practice 9.1

Do not use the same name for an argument passed to a function and the corresponding parameter in the function definition. Using different names avoids ambiguity.

## Common Programming Error 9.2

Redefining a function parameter as a local variable in the function is a logic error.

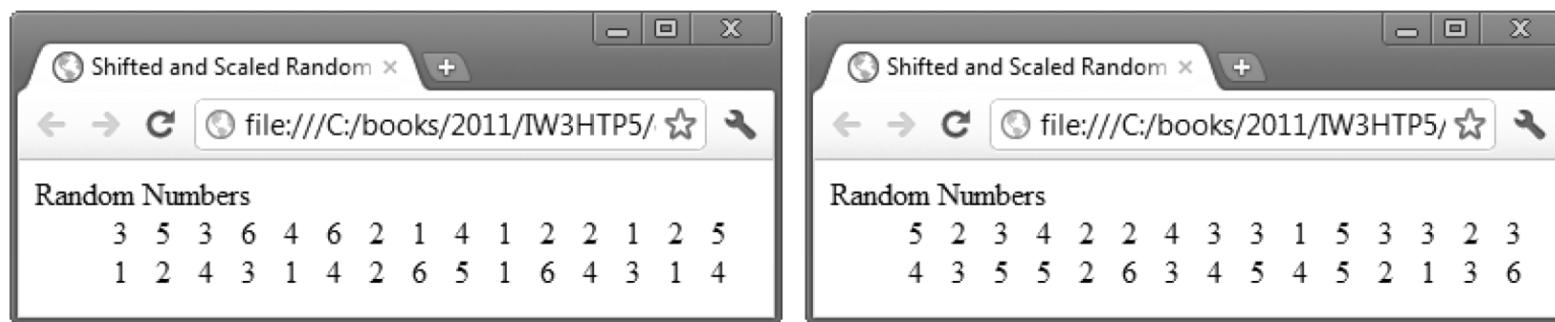

## 9.5 Random Number Generation

- **random** method generates a floating-point value from 0.0 up to, but not including, 1.0
- Random integers in a certain range can be generated by scaling and shifting the values returned by random, then using **Math.floor** to convert them to integers
  - The scaling factor determines the size of the range (i.e. a scaling factor of 4 means four possible integers)
  - The shift number is added to the result to determine where the range begins (i.e. shifting the numbers by 3 would give numbers between 3 and 7)
- Method **Math.floor** rounds its argument down to the closest integer

```

5 <html>
6   <head>
7     <meta charset = "utf-8">
8     <title>Shifted and Scaled Random Integers</title>
9     <style type = "text/css">
10       p, ol { margin: 0; }
11       li { display: inline; margin-right: 10px; }
12     </style>
13     <script>
14
15       var value;
16
17       document.writeln( "<p>Random Numbers</p><ol>" );
18
19       for ( var i = 1; i <= 30; ++i )
20     {
21         value = Math.floor( 1 + Math.random() * 6 );
22         document.writeln( "<li>" + value + "</li>" );
23     } // end for
24
```

## 9.5.2 Displaying Random Images

- In the next example, we build a random image generator—a script that displays four randomly selected die images every time the user clicks a Roll Dice button on the page
- For the script in Fig. 9.5 to function properly, the directory containing the file RollDice.html must also contain the six die images—these are included with this chapter’s examples

## 9.5.2 Displaying Random Images

- Until now, all user interactions with scripts have been through
  - A prompt dialog
  - An alert dialog
- These dialogs are valid ways to receive input from a user and to display messages, but they're fairly limited in their capabilities
- A prompt dialog can obtain only one value at a time from the user, and a message dialog can display only one message
- Inputs are typically received from the user via an **HTML5 form**

## 9.5.2 Displaying Random Images

- Outputs are typically displayed to the user in the web page
- This program uses an HTML5 form and a new graphical user interface concept
  - GUI event handling
- The JavaScript executes in response to the user's interaction with an element in a form
- This interaction causes an event
- Scripts are often used to respond to user initiated events

11       ul { margin: 0; }
12     </style>
13     <script>
14       // variables used to interact with the img elements
15       var die1Image;
16       var die2Image;
17       var die3Image;
18       var die4Image;
19
```

**Fig. 9.5** | Random dice image generation using Math.random. (Part 1 of 4.)

```
20 // register button listener and get the img elements
21 function start()
22 {
23     var button = document.getElementById( "rollButton" );
24     button.addEventListener( "click", rollDice, false );
25     die1Image = document.getElementById( "die1" );
26     die2Image = document.getElementById( "die2" );
27     die3Image = document.getElementById( "die3" );
28     die4Image = document.getElementById( "die4" );
29 } // end function rollDice
30
31 // roll the dice
32 function rollDice()
33 {
34     setImage( die1Image );
35     setImage( die2Image );
36     setImage( die3Image );
37     setImage( die4Image );
38 } // end function rollDice
39
```

**Fig. 9.5** | Random dice image generation using `Math.random`. (Part 2 of 4.)

```
40     // set image source for a die
41     function setImage( dieImg )
42     {
43         var dieValue = Math.floor( 1 + Math.random() * 6 );
44         dieImg.setAttribute( "src", "die" + dieValue + ".png" );
45         dieImg.setAttribute( "alt",
46             "die image with " + dieValue + " spot(s)" );
47     } // end function setImage
48
49     window.addEventListener( "load", start, false );
50
51 </script>
52 </head>
```

55         </form>
56         <ol>
57             <li><img id = "die1" src = "blank.png" alt = "die 1 image"></li>
58             <li><img id = "die2" src = "blank.png" alt = "die 2 image"></li>
59             <li><img id = "die3" src = "blank.png" alt = "die 3 image"></li>
60             <li><img id = "die4" src = "blank.png" alt = "die 4 image"></li>
61         </ol>
62     </body>
63 </html>
```

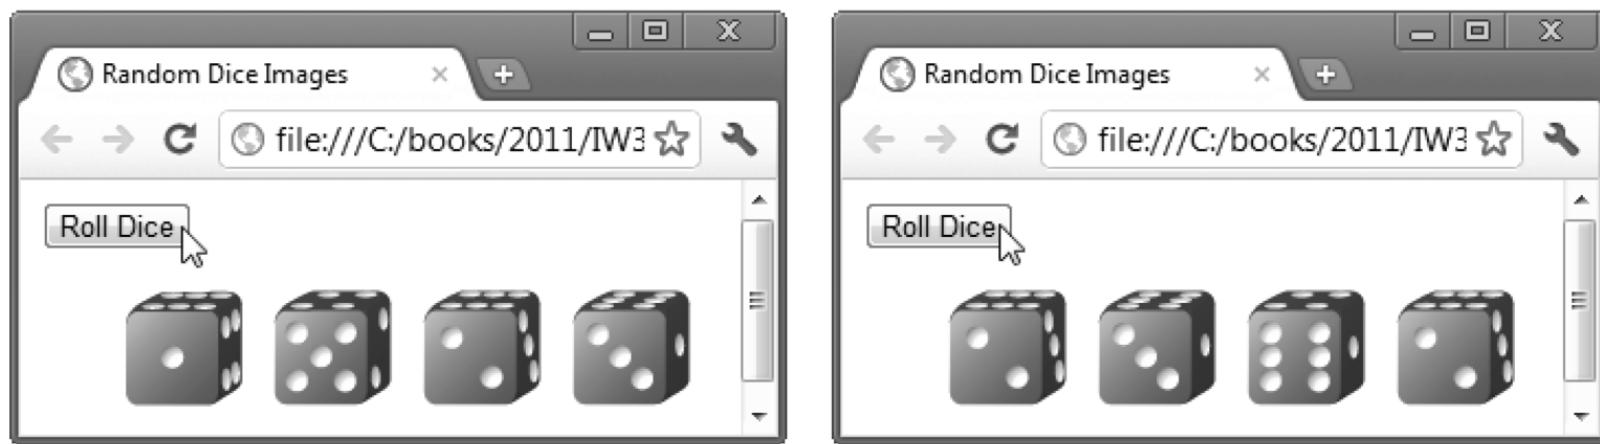

Fig. 9.5 | Random dice image generation using Math.random. (Part 4 of 4.)

## 9.5.2 Displaying Random Images

- The body element
  - The elements in the body are used extensively in the script
- The form element
  - The HTML5 standard requires that every form contains an action attribute
  - Because this form does not post its information to a web server, the string "#" is used simply to allow this document to validate
  - The # symbol by itself represents the current page

## 9.5.2 Displaying Random Images

- Event-driven programming
  - The user interacts with an element in the web page, the script is notified of the event and the script processes the event
  - The user's interaction with the GUI “drives” the program
  - The button click is known as the event
  - The function that's called when an event occurs is known as an event handler
  - When a GUI event occurs in a form, the browser calls the specified event-handling function

## 9.5.2 Displaying Random Images

- Before any event can be processed, each element must know which event-handling function will be called when a particular event occurs

## 9.5.2 Displaying Random Images

- The **img** Elements
  - The four **img** elements will display the four randomly selected dice
  - Their **id** attributes (die1, die2, die3 and die4, respectively) can be used to apply CSS styles and to enable script code to refer to these element in the HTML5 document
  - Because the **id** attribute, if specified, must have a unique value among all id attributes in the page, Java-Script can reliably refer to any single element via its **id** attribute
  - Each **img** element displays the image blank.png (an empty white image) when the page first renders

## 9.5.2 Displaying Random Images

- Specifying a Function to Call When the Browser Finishes Loading a Document
  - Many examples will execute a JavaScript function when the document finishes loading
  - This is accomplished by handling the window object's load event
- To specify the function to call when an event occurs, you register an event handler for that event
- Method **addEventListener** is available for every DOM node

## 9.5.2 Displaying Random Images

- The method takes three arguments
  - The first is the name of the event for which we're registering a handler
  - The second is the function that will be called to handle the event
  - The last argument is typically false—the true value is beyond this book's scope
- **window.addEventListener( "load", start, false );**
- [http://www.w3schools.com/jsref/met\\_document\\_addeventlistener.asp](http://www.w3schools.com/jsref/met_document_addeventlistener.asp)
- <http://javascript.info/tutorial/bubbling-and-capturing>

## 9.5.3 Rolling Dice Repeatedly and Displaying Statistics

- To show that the random values representing the dice occur with approximately equal likelihood
  - Let's allow the user to roll 12 dice at a time and keep statistics showing the number of times each face occurs and the percentage of the time each face is rolled (Fig. 9.6)

## 9.5.3 Rolling Dice Repeatedly and Displaying Statistics

- Generalized scaling and shifting of random values
- The values returned by random are always in the range
  - $0.0 < \text{Math.random}() < 1.0$
- Previously, we demonstrated the statement
  - `face = Math.floor( 1 + Math.random() * 6 );`  
which simulates the rolling of a six-sided die
- This statement always assigns an integer (at random) to variable face, in the range  $1 \leq \text{face} \leq 6$

## 9.5.3 Rolling Dice Repeatedly and Displaying Statistics (cont.)

- Referring to the preceding statement, we see that the width of the range is determined by the number used to scale random with the multiplication operator
- We can generalize this result as
  - **face = Math.floor( a + Math.random() \* b );**
  - **a** is the shifting value (which is equal to the first number in the desired range of consecutive integers)
  - **b** is the scaling factor (which is equal to the width of the desired range of consecutive integers)

**Fig. 9.6 |** Rolling 12 dice and displaying frequencies. (Part 9 of 9.)

## 9.6 Example: Game of Chance

- The script in Fig. 9.7 simulates the game of craps
  - A player rolls two dice
  - After the dice have come to rest, the sum of the spots on the two upward faces is calculated
  - If the sum is 7 or 11 on the first throw, the player wins
  - If the sum is 2, 3 or 12 on the first throw (called “craps”), the player loses (i.e., the “house” wins)
  - If the sum is 4, 5, 6, 8, 9 or 10 on the first throw, that sum becomes the player’s “point”
  - To win, you must continue rolling the dice until you “make your point” (i.e., roll your point value)
  - You lose by rolling a 7 before making the point

## 9.6 Example: Game of Chance;

- The HTML5 audio Element
  - An HTML5 audio element is used to embed audio into a web page
  - We specify an **id** for the element, so that we can programmatically control when the audio clip plays, based on the user's interactions with the game
  - Setting the preload attribute to "auto" indicates to the browser that it should consider downloading the audio clip so that it's ready to be played when the game needs it
    - `<audio id = "dicerolling" preload = "auto">`

## 9.6 Example: Game of Chance;

- Most browsers support MP3, OGG and/or WAV format
- Each source element specifies a **src** and a **type** attribute
  - The **src** attribute specifies the location of the audio clip
  - The **type** attribute specifies the clip's MIME type—audio/mpeg for the MP3 clip and audio/ogg for the OGG clip (WAV would be audio/x-wav; MIME types for these and other formats can be found online)
- When a web browser that supports the audio element encounters the source elements, it will chose the first audio source that represents one of the browser's supported formats
  - [http://www.w3schools.com/html/html5\\_audio.asp](http://www.w3schools.com/html/html5_audio.asp)

### **Software Engineering Observation 9.3**

---

Variables declared inside the body of a function are known only in that function. If the same variable names are used elsewhere in the program, they'll be entirely separate variables in memory.

### **Error-Prevention Tip 9.1**

---

Initializing variables when they're declared in functions helps avoid incorrect results and interpreter messages warning of uninitialized data.

## 9.7 Scope Rules

- Each identifier in a program has a scope
- The scope of an identifier for a variable or function is the portion of the program in which the identifier can be referenced
- Global variables or script-level variables are accessible in any part of a script and are said to have global scope
  - Thus every function in the script can potentially use the variables

## 9.7 Scope Rules (Cont.)

- Identifiers declared inside a function have function (or local) scope and can be used only in that function
- Function scope begins with the opening left brace ({) of the function in which the identifier is declared and ends at the terminating right brace (})
- Local variables of a function and function parameters have function scope
- If a local variable in a function has the same name as a global variable
  - The global variable is “hidden” from the body of the function

## **Good Programming Practice 9.2**

---

Avoid local-variable names that hide global-variable names. This can be accomplished by simply avoiding the use of duplicate identifiers in a script.

# 9.8 JavaScript Global Functions

- JavaScript provides nine global functions as part of a Global object
- This object contains
  - All the global variables in the script
  - All the user-defined functions in the script
  - All the built-in global functions listed in the following slide
- You do not need to use the Global object directly; JavaScript uses it for you
  - [http://www.w3schools.com/jsref/jsref\\_obj\\_global.asp](http://www.w3schools.com/jsref/jsref_obj_global.asp)

Global function	Description
<code>isFinite</code>	Takes a numeric argument and returns <code>true</code> if the value of the argument is not <code>Nan</code> , <code>Number.POSITIVE_INFINITY</code> or <code>Number.NEGATIVE_INFINITY</code> (values that are not numbers or numbers outside the range that JavaScript supports)—otherwise, the function returns <code>false</code> .
<code>isNaN</code>	Takes a numeric argument and returns <code>true</code> if the value of the argument is not a number; otherwise, it returns <code>false</code> . The function is commonly used with the return value of <code>parseInt</code> or <code>parseFloat</code> to determine whether the result is a proper numeric value.
<code>parseFloat</code>	Takes a string argument and attempts to convert the <i>beginning</i> of the string into a floating-point value. If the conversion is unsuccessful, the function returns <code>Nan</code> ; otherwise, it returns the converted value (e.g., <code>parseFloat( "abc123.45" )</code> returns <code>Nan</code> , and <code>parseFloat( "123.45abc" )</code> returns the value <code>123.45</code> ).

**Fig. 9.10 |** JavaScript global functions. (Part I of 2.)

Global function	Description
parseInt	<p>Takes a string argument and attempts to convert the beginning of the string into an integer value. If the conversion is unsuccessful, the function returns NaN; otherwise, it returns the converted value (for example, <code>parseInt( "abc123" )</code> returns NaN, and <code>parseInt( "123abc" )</code> returns the integer value 123). This function takes an optional second argument, from 2 to 36, specifying the radix (or base) of the number. Base 2 indicates that the first argument string is in binary format, base 8 that it's in octal format and base 16 that it's in hexadecimal format. See Appendix E, for more information on binary, octal and hexadecimal numbers.</p>

## 9.9 Recursion

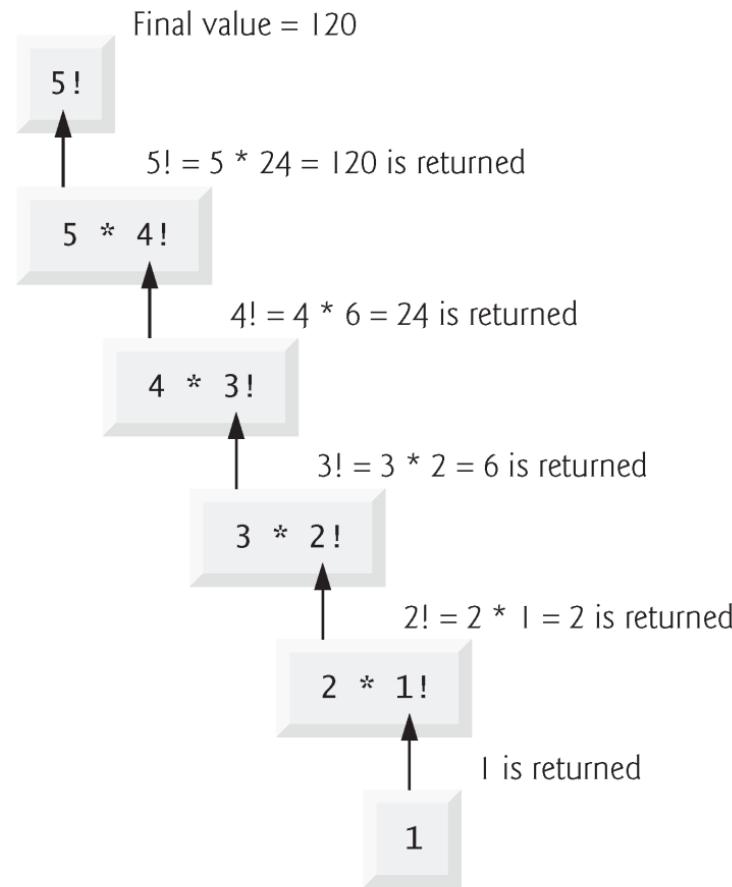

- A recursive function calls itself, either directly, or indirectly through another function
- A recursive function knows how to solve only the simplest case, or base case
  - If the function is called with a base case, it returns a result
  - If the function is called with a more complex problem, it divides the problem into two conceptual pieces—a piece that the function knows how to process (the base case) and a simpler or smaller version of the original problem
- The function invokes (calls) a fresh copy of itself to go to work on the smaller problem; this invocation is referred to as a recursive call, or the recursion step

## 9.10 Recursion (Cont.)

- The recursion step executes while the original call to the function is still open (i.e., it has not finished executing)
- For recursion eventually to terminate, each time the function calls itself with a simpler version of the original problem, the sequence of smaller and smaller problems must converge on the base case
  - At that point, the function recognizes the base case, returns a result to the previous copy of the function, and a sequence of returns ensues up the line until the original function call eventually returns the final result to the caller

(a) Sequence of recursive calls.

(b) Values returned from each recursive call.

## Common Programming Error 9.3

---

Omitting the base case and writing the recursion step incorrectly so that it does not converge on the base case are both errors that cause infinite recursion, eventually exhausting memory. This situation is analogous to the problem of an infinite loop in an iterative (non-recursive) solution.

## Error-Prevention Tip 9.2

---

Internet Explorer displays an error message when a script seems to be going into infinite recursion. Firefox simply terminates the script after detecting the problem. This allows the user of the web page to recover from a script that contains an infinite loop or infinite recursion.

## 9.10 Recursion vs. Iteration

- Both iteration and recursion involve repetition
  - Iteration explicitly uses a repetition statement
  - Recursion achieves repetition through repeated function calls
- Iteration and recursion each involve a termination test
  - Iteration terminates when the loop-continuation condition fails
  - Recursion terminates when a base case is recognized

## 9.11 Recursion vs. Iteration

- Iteration both with counter-controlled repetition and recursion gradually approach termination
  - Iteration keeps modifying a counter until the counter assumes a value that makes the loop-continuation condition fail
  - Recursion keeps producing simpler versions of the original problem until the base case is reached
- Both iteration and recursion can occur infinitely
  - An infinite loop occurs with iteration if the loop-continuation test never becomes false
  - infinite recursion occurs if the recursion step does not reduce the problem each time via a sequence that converges on the base case or if the base case is incorrect

## Software Engineering Observation 9.4

---

Any problem that can be solved recursively can also be solved iteratively (non-recursively). A recursive approach is normally chosen in preference to an iterative approach when the recursive approach more naturally mirrors the problem and results in a program that's easier to understand and debug. Another reason to choose a recursive solution is that an iterative solution may not be apparent.

## Performance Tip 9.1

---

Avoid using recursion in performance-critical situations. Recursive calls take time and consume additional memory.
